In a closely related working paper called *Reservation Employer Establishments: Data from the U.S. Census Longitudinal Business Database*, Akee, Mykerezi, and Todd (2017) describe the employer segment of the reservation economy, in terms of per capita employer counts and the per capita number of jobs provided by reservation employers, as compared to the economy of nearby county areas. Regressions that relate these two per capita outcomes (number of establishments and number of jobs) to population level, a reservation dummy variable, and in some cases additional control variables are used to show how reservation versus county differences vary with the level of population. The statistical significance of these differences is assessed by computing distributions of reservation versus county outcomes based on multiple random draws of reservation and county regression equation coefficients, using the estimated variance-covariance matrix of the regression coefficients. However, Akee, Mykerezi, and Todd 2017 do not give full documentation of either their estimated coefficients and variance-covariance matrices or the reservation versus county differences in establishment and job numbers. This supplement to their work provides a comprehensive list of their regression results as well as a complete graphical summary of how the reservation-versus-county differences in establishment and job numbers implied by these regressions vary with population levels.

Appendix 1 below lists the regression coefficients, variance-covariance matrices, and other regression statistics for both establishment counts and job numbers in the 18 separate industrial sectors shown in Table 1. For each sector and both establishments and jobs, we provide 6 regression specifications—ordinary least squares (OLS) and weighted least squares (WLS) for three different sets of right-hand side variables. This results in 216 tables of regression results (18x2x6). The regression output tables are group by sector in the order shown in Table 1, and within each sector we first show results for the 6 specifications of establishments per capita and then results for the 6 specifications of jobs per capita. For both establishments and jobs per capital, the first and most parsimonious specification whose results are shown corresponds to the following regression:

Equation 1:

$$\left(\frac{E}{P}\right)_i = \alpha + \beta_1 Population_i + \beta_2 Population_i^2 + \beta_3 Reservation_i \\ + \beta_4(Reservation_i \times Population_i) + \beta_5(Reservation_i \times Population_i^2) + \varepsilon_i$$

The outcome variable  $(E/P)_i$  is either establishments or jobs per capita for the  $i^{\text{th}}$  area (a reservation or one of the included “county complement” areas described in Akee, Mykerezi and Todd 2017) in 2010. We conduct this analysis separately for each of our 18 2-digit NAICS categories. There is a common intercept term included in the model. The variable Reservation equals 1 if the observation is an American Indian reservation and is 0 if it is a county area. To allow for a nonlinear relationship between P and E, we include a simple count of population for the geographic unit as well as its squared term in the regression, and we interact the reservation indicator variable with these two population measures. This full set of interaction terms allows counties and reservations to have fully independent E-P relationships. The random variable  $\varepsilon_i$  represents the error term. The first regression specification in the tables below includes only these variables and is referred to as the 6-variable regression. In the tables’ column headers, P stands for population and R for the reservation dummy variable.

We estimate two more specifications that include additional control variables. The 8-variable regression adds population density (square miles of land area per person) and a dummy variable for “rural” location that is based on the U.S. Department of Agriculture’s Rural-Urban Continuum Codes for 2013. The 11-variable regression further adds per capital income, the poverty rate, and the percentage of the population 25-years old or older with a Bachelors’ degree. See Akee, Mykerezi, and Todd 2017 for details on the definition of these variables.

Appendix 2 uses the fitted coefficients and variance-covariance matrices in Appendix 1 to graph how the fitted distributions of reservation and county establishment and job numbers vary with local area population levels. For further information, see the discussion of Tables 6-11 and Figures 6 and 7 in Akee, Mykerezi, and Todd 2017. As in Appendix 1, the results are show by sector, first for establishment counts and then for job numbers. Results are shown the 6-, 8-, and 11-variable models but only for Akee, Mykerezi, and Todd’s preferred WLS specification. Two different views are shown, one showing the distributions of both the reservation and county area numbers and one showing the distribution of their difference (“gap”), or county number minus reservation number.

**Table 1: Establishment Overview by Industry**

Industry	NAICS code(s)
Agriculture, Forestry, Fishing and Hunting	11
Mining, Quarrying, and Oil and Gas Extraction	21
Utilities	22
Construction	23
Manufacturing	31, 32, 33
Wholesale Trade	42
Retail Trade	44, 45
Transportation and Warehousing	48, 49
Information	51
Finance and Insurance AND Real Estate and Rental and Leasing	52, 53
Professional, Scientific, and Technical Services	54
Management of Companies and Enterprises; Administrative and Support; and Waste Management and Remediation Services	55, 56
Educational Services	61
Health Care and Social Assistance	62
Arts, Entertainment, and Recreation	71
Accommodation and Food Services	72
Other Services (except Public Administration)	81
Public Administration	92
